MapReduce

From Wikipedia, the free encyclopedia

MapReduce is a programming model and an associated implementation for processing and generating large data sets with a parallel, distributed algorithm on a cluster.[1][2]

A MapReduce program is composed of a **Map()** procedure that performs filtering and sorting (such as sorting students by first name into queues, one queue for each name) and a **Reduce()** procedure that performs a summary operation (such as counting the number of students in each queue, yielding name frequencies). The "MapReduce System" (also called "infrastructure" or "framework") orchestrates the processing by marshalling the distributed servers, running the various tasks in parallel, managing all communications and data transfers between the various parts of the system, and providing for redundancy and fault tolerance.

The model is inspired by the map and reduce functions commonly used in functional programming,[3] although their purpose in the MapReduce framework is not the same as in their original forms.[4] The key contributions of the MapReduce framework are not the actual map and reduce functions, but the scalability and fault-tolerance achieved for a variety of applications by optimizing the execution engine once. As such, a single-threaded implementation of MapReduce (such as MongoDB) will usually not be faster than a traditional (non-MapReduce) implementation, any gains are usually only seen with multi-threaded implementations.[5] Only when the optimized distributed shuffle operation (which reduces network communication cost) and fault tolerance features of the MapReduce framework come into play, is the use of this model beneficial. Optimizing the communication cost is essential to a good MapReduce algorithm.[6]

MapReduce libraries have been written in many programming languages, with different levels of optimization. A popular open-source implementation that has support for distributed shuffles is part of Apache Hadoop. The name MapReduce originally referred to the proprietary Google technology, but has since been genericized.

Contents

Overview

MapReduce is a framework for processing parallelizable problems across huge datasets using a large number of computers (nodes), collectively referred to as a cluster (if all nodes are on the same local network and use similar hardware) or a grid (if the nodes are shared across geographically and administratively distributed systems, and use more heterogenous hardware). Processing can occur on data stored either in a filesystem (unstructured) or in a database (structured). MapReduce can take advantage of locality of data, processing it on or near the storage assets in order to reduce the distance over which it must be transmitted.

- **"Map" step:** Each worker node applies the "map()" function to the local data, and writes the output to a temporary storage. A master node orchestrates that for redundant copies of input data, only one is processed.
- **"Shuffle" step:** Worker nodes redistribute data based on the output keys (produced by the "map()" function), such that all data belonging to one key is located on the same worker node.
- **"Reduce" step:** Worker nodes now process each group of output data, per key, in parallel.

MapReduce allows for distributed processing of the map and reduction operations. Provided that each mapping operation is independent of the others, all maps can be performed in parallel – though in practice this is limited by the number of independent data sources and/or the number of CPUs near each source. Similarly, a set of 'reducers' can perform the reduction phase, provided that all outputs of the map operation that share the same key are presented to the same reducer at the same time, or that the reduction function is associative. While this process can often appear inefficient compared to algorithms that are more sequential, MapReduce can be applied to significantly larger datasets than "commodity" servers can handle – a large server farm can use MapReduce to sort a petabyte of data in only a few hours.[7] The parallelism also offers some possibility of recovering from partial failure of servers or storage during the operation: if one mapper or reducer fails, the work can be rescheduled – assuming the input data is still available.

Another way to look at MapReduce is as a 5-step parallel and distributed computation:

1. **Prepare the Map() input** – the "MapReduce system" designates Map processors, assigns the input key value *K1* that each processor would work on, and provides that processor with all the

input data associated with that key value.

2. **Run the user-provided Map() code** – Map() is run exactly once for each *K1* key value, generating output organized by key values *K2*.

3. **"Shuffle" the Map output to the Reduce processors** – the MapReduce system designates Reduce processors, assigns the *K2* key value each processor should work on, and provides that processor with all the Map-generated data associated with that key value.

4. **Run the user-provided Reduce() code** – Reduce() is run exactly once for each *K2* key value produced by the Map step.

5. **Produce the final output** – the MapReduce system collects all the Reduce output, and sorts it by *K2* to produce the final outcome.

These five steps can be Logically thought of as running in sequence – each step starts only after the previous step is completed – although in practice they can be interleaved as long as the final result is not affected.

In many situations, the input data might already be distributed ("sharded") among many different servers, in which case step 1 could sometimes be greatly simplified by assigning Map servers that would process the locally present input data. Similarly, step 3 could sometimes be sped up by assigning Reduce processors that are as close as possible to the Map-generated data they need to process.

Logical view

The *Map* and *Reduce* functions of *MapReduce* are both defined with respect to data structured in (key, value) pairs. *Map* takes one pair of data with a type in one data domain, and returns a list of pairs in a different domain:

```
Map(k1,v1) → list(k2,v2)
```

The *Map* function is applied in parallel to every pair in the input dataset. This produces a list of pairs for each call. After that, the MapReduce framework collects all pairs with the same key from all lists and groups them together, creating one group for each key.

The *Reduce* function is then applied in parallel to each group, which in turn produces a collection of values in the same domain:

```
Reduce(k2, list (v2)) → list(v3)
```

Each *Reduce* call typically produces either one value v3 or an empty return, though one call is allowed to return more than one value. The returns of all calls are collected as the desired result list.

Thus the MapReduce framework transforms a list of (key, value) pairs into a list of values. This behavior is different from the typical functional programming map and reduce combination, which accepts a list of arbitrary values and returns one single value that combines *all* the values returned by map.

It is necessary but not sufficient to have implementations of the map and reduce abstractions in order to implement MapReduce. Distributed implementations of MapReduce require a means of connecting the processes performing the Map and Reduce phases. This may be a distributed file system. Other options

are possible, such as direct streaming from mappers to reducers, or for the mapping processors to serve up their results to reducers that query them.

Examples

The prototypical MapReduce example counts the appearance of each word in a set of documents:[8]

```
function map(String name, String document):
  // name: document name
  // document: document contents
  for each word w in document:
    emit (w, 1)

function reduce(String word, Iterator partialCounts):
  // word: a word
  // partialCounts: a list of aggregated partial counts
  sum = 0
  for each pc in partialCounts:
    sum += ParseInt(pc)
  emit (word, sum)
```

Here, each document is split into words, and each word is counted by the *map* function, using the word as the result key. The framework puts together all the pairs with the same key and feeds them to the same call to *reduce*. Thus, this function just needs to sum all of its input values to find the total appearances of that word.

As another example, imagine that for a database of 1.1 billion people, one would like to compute the average number of social contacts a person has according to age. In SQL, such a query could be expressed as:

```
  SELECT age, AVG(contacts)
    FROM social.person
GROUP BY age
ORDER BY age
```

Using MapReduce, the K1 key values could be the integers 1 through 1100, each representing a batch of 1 million records, the K2 key value could be a person's age in years, and this computation could be achieved using the following functions:

```
function Map is
    input: integer K1 between 1 and 1100, representing a batch of 1 million social.person records
    for each social.person record in the K1 batch do
        let Y be the person's age
        let N be the number of contacts the person has
        produce one output record (Y,(N,1))
    repeat
end function

function Reduce is
    input: age (in years) Y
    for each input record (Y,(N,C)) do
        Accumulate in S the sum of N*C
        Accumulate in C_new the sum of C
    repeat
    let A be S/C_new
    produce one output record (Y,(A,C_new))
end function
```

The MapReduce System would line up the 1100 Map processors, and would provide each with its corresponding 1 million input records. The Map step would produce 1.1 billion (Y,(N,1)) records, with Y values ranging between, say, 8 and 103. The MapReduce System would then line up the 96 Reduce

processors by performing shuffling operation of the key/value pairs due to the fact that we need average per age, and provide each with its millions of corresponding input records. The Reduce step would result in the much reduced set of only 96 output records `(Y,A)`, which would be put in the final result file, sorted by `Y`.

The count info in the record is important if the processing is reduced more than one time. If we did not add the count of the records, the computed average would be wrong, for example:

```
-- map output #1: age, quantity of contacts
10, 9
10, 9
10, 9
```

```
-- map output #2: age, quantity of contacts
10, 9
10, 9
```

```
-- map output #3: age, quantity of contacts
10, 10
```

If we reduce files `#1` and `#2`, we will have a new file with an average of 9 contacts for a 10 year old person ((9+9+9+9+9)/5):

```
-- reduce step #1: age, average of contacts
10, 9
```

If we reduce it with file `#3`, we lose the count of how many records we've already seen, so we end up with an average of 9.5 contacts for a 10 year old person ((9+10)/2), which is wrong. The correct answer is 9.17 ((9+9+9+9+9+10)/6).

Dataflow

The frozen part of the MapReduce framework is a large distributed sort. The hot spots, which the application defines, are:

- an *input reader*
- a *Map* function
- a *partition* function
- a *compare* function
- a *Reduce* function
- an *output writer*

Input reader

The *input reader* divides the input into appropriate size 'splits' (in practice typically 64 MB to 128 MB) and the framework assigns one split to each *Map* function. The *input reader* reads data from stable storage (typically a distributed file system) and generates key/value pairs.

A common example will read a directory full of text files and return each line as a record.

Map function

The *Map* function takes a series of key/value pairs, processes each, and generates zero or more output key/value pairs. The input and output types of the map can be (and often are) different from each other.

If the application is doing a word count, the map function would break the line into words and output a key/value pair for each word. Each output pair would contain the word as the key and the number of instances of that word in the line as the value.

Partition function

Each *Map* function output is allocated to a particular *reducer* by the application's *partition* function for sharding purposes. The *partition* function is given the key and the number of reducers and returns the index of the desired *reducer*.

A typical default is to hash the key and use the hash value modulo the number of *reducers*. It is important to pick a partition function that gives an approximately uniform distribution of data per shard for load-balancing purposes, otherwise the MapReduce operation can be held up waiting for slow reducers (reducers assigned more than their share of data) to finish.

Between the map and reduce stages, the data is *shuffled* (parallel-sorted / exchanged between nodes) in order to move the data from the map node that produced it to the shard in which it will be reduced. The shuffle can sometimes take longer than the computation time depending on network bandwidth, CPU speeds, data produced and time taken by map and reduce computations.

Comparison function

The input for each *Reduce* is pulled from the machine where the *Map* ran and sorted using the application's *comparison* function.

Reduce function

The framework calls the application's *Reduce* function once for each unique key in the sorted order. The *Reduce* can iterate through the values that are associated with that key and produce zero or more outputs.

In the word count example, the *Reduce* function takes the input values, sums them and generates a single output of the word and the final sum.

Output writer

The *Output Writer* writes the output of the *Reduce* to the stable storage, usually a distributed file system.

Performance considerations

MapReduce programs are not guaranteed to be fast. The main benefit of this programming model is to exploit the optimized shuffle operation of the platform, and only having to write the *Map* and *Reduce* parts of the program. In practice, the author of a MapReduce program however has to take the shuffle step into consideration; in particular the partition function and the amount of data written by the *Map* function can have a large impact on the performance. Additional modules such as the *Combiner* function can help to reduce the amount of data written to disk, and transmitted over the network.

When designing a MapReduce algorithm, the author needs to choose a good tradeoff[6] between the computation and the communication costs. Communication cost often dominates the computation cost,[6] and many MapReduce implementations are designed to write all communication to distributed storage for crash recovery.

For processes that complete fast, and where the data fits into main memory of a single machine or a small cluster, using a MapReduce framework usually is not effective: since these frameworks are designed to recover from the loss of whole nodes during the computation, they write interim results to distributed storage. This crash recovery is expensive, and only pays off when the computation involves many computers and a long runtime of the computation - a task that completes in seconds can just be restarted in the case of an error; and the likelihood of at least one machine failing grows quickly with the cluster size. On such problems, implementations keeping all data in memory and simply restarting a computation on node failures, or - when the data is small enough - non-distributed solutions will often be faster than a MapReduce system.

Distribution and reliability

MapReduce achieves reliability by parceling out a number of operations on the set of data to each node in the network. Each node is expected to report back periodically with completed work and status updates. If a node falls silent for longer than that interval, the master node (similar to the master server in the Google File System) records the node as dead and sends out the node's assigned work to other nodes. Individual operations use atomic operations for naming file outputs as a check to ensure that there are not parallel conflicting threads running. When files are renamed, it is possible to also copy them to another name in addition to the name of the task (allowing for side-effects).

The reduce operations operate much the same way. Because of their inferior properties with regard to parallel operations, the master node attempts to schedule reduce operations on the same node, or in the same rack as the node holding the data being operated on. This property is desirable as it conserves bandwidth across the backbone network of the datacenter.

Implementations are not necessarily highly reliable. For example, in older versions of Hadoop the *NameNode* was a single point of failure for the distributed filesystem. Later versions of Hadoop have high availability with an active/passive failover for the "NameNode."

Uses

MapReduce is useful in a wide range of applications, including distributed pattern-based searching, distributed sorting, web link-graph reversal, Singular Value Decomposition,[9] web access log stats, inverted index construction, document clustering, machine learning,[10] and statistical machine translation. Moreover, the MapReduce model has been adapted to several computing environments like multi-core and many-core systems,[11][12][13] desktop grids,[14] volunteer computing environments,[15] dynamic cloud environments,[16] and mobile environments.[17]

At Google, MapReduce was used to completely regenerate Google's index of the World Wide Web. It replaced the old *ad hoc* programs that updated the index and ran the various analyses.[18] Development at Google has since moved on to technologies such as Percolator, Flume and MillWheel that offer streaming operation and updates instead of batch processing, to allow integrating "live" search results without rebuilding the complete index.

MapReduce's stable inputs and outputs are usually stored in a distributed file system. The transient data is usually stored on local disk and fetched remotely by the reducers.

Criticism

Lack of novelty

David DeWitt and Michael Stonebraker, computer scientists specializing in parallel databases and shared-nothing architectures, have been critical of the breadth of problems that MapReduce can be used for.[19] They called its interface too low-level and questioned whether it really represents the paradigm shift its proponents have claimed it is.[20] They challenged the MapReduce proponents' claims of novelty, citing Teradata as an example of prior art that has existed for over two decades. They also compared MapReduce programmers to Codasyl programmers, noting both are "writing in a low-level language performing low-level record manipulation."[20] MapReduce's use of input files and lack of schema support prevents the performance improvements enabled by common database system features such as B-trees and hash partitioning, though projects such as Pig (or PigLatin), Sawzall, Apache Hive,[21] YSmart (http://ysmart.cse.ohio-state.edu/),[22] HBase[23] and BigTable[23][24] are addressing some of these problems.

Greg Jorgensen wrote an article rejecting these views.[25] Jorgensen asserts that DeWitt and Stonebraker's entire analysis is groundless as MapReduce was never designed nor intended to be used as a database.

DeWitt and Stonebraker have subsequently published a detailed benchmark study in 2009 comparing performance of Hadoop's MapReduce and RDBMS approaches on several specific problems.[26] They concluded that relational databases offer real advantages for many kinds of data use, especially on complex processing or where the data is used across an enterprise, but that MapReduce may be easier for users to adopt for simple or one-time processing tasks.

Google has been granted a patent on MapReduce.[27] However, there have been claims that this patent should not have been granted because MapReduce is too similar to existing products. For example, map and reduce functionality can be very easily implemented in Oracle's PL/SQL database oriented language[28] or is transparently for developers supported in distributed database architectures such as Clusterpoint XML database[29] or MongoDB NoSQL database.[30]

Restricted programming framework

MapReduce tasks must be written as acyclic dataflow programs, i.e. a stateless mapper followed by a stateless reducer, that are executed by a batch job scheduler. This paradigm makes repeated querying of datasets difficult and imposes limitations that are felt in fields such as machine learning, where iterative algorithms that revisit a single working set multiple times are the norm.[31]

Conferences and users groups

- The First International Workshop on MapReduce and its Applications (MAPREDUCE'10) (http://graal.ens-lyon.fr/mapreduce/) was held in June 2010 with the HPDC conference and OGF'29 meeting in Chicago, IL.

- MapReduce Users Groups (http://mapreduce.meetup.com/) around the world.

Papers

- "CloudSVM: Training an SVM Classifier in Cloud Computing Systems" (http://www.researchgate.net/publication/259226804_A_MapReduce_based_distributed_SVM_algorithm_for_binary_classification)-paper by F. Ozgur Catak, M. Erdal Balaban, Springer, Lecture Notes in Computer Science,Pervasive Computing and Networked World 2012 from TÜBİTAK and Istanbul University
- "A Hierarchical Framework for Cross-Domain MapReduce Execution" (http://dl.acm.org/citation.cfm?id=1996023.1996026) — paper by Yuan Luo, Zhenhua Guo, Yiming Sun, Beth Plale, Judy Qiu; from Indiana University and Wilfred Li; from University of California, San Diego
- "Interpreting the Data: Parallel Analysis with Sawzall" (http://research.google.com/archive/sawzall.html) — paper by Rob Pike, Sean Dorward, Robert Griesemer, Sean Quinlan; from Google Labs
- "Evaluating MapReduce for Multi-core and Multiprocessor Systems" (http://csl.stanford.edu/%7Echristos/publications/2007.cmp_mapreduce.hpca.pdf) — paper by Colby Ranger, Ramanan Raghuraman, Arun Penmetsa, Gary Bradski, and Christos Kozyrakis; from Stanford University
- "Why MapReduce Matters to SQL Data Warehousing" (http://www.dbms2.com/2008/08/26/why-mapreduce-matters-to-sql-data-warehousing/) — analysis related to the August, 2008 introduction of MapReduce/SQL integration by Aster Data Systems and Greenplum
- "MapReduce for the Cell B.E. Architecture" (http://pages.cs.wisc.edu/~dekruijf/docs/mapreduce-cell.pdf) — paper by Marc de Kruijf and Karthikeyan Sankaralingam; from University of Wisconsin–Madison
- "Mars: A MapReduce Framework on Graphics Processors" (http://www.cse.ust.hk/catalac/users/saven/GPGPU/MapReduce/PACT08/171.pdf) — paper by Bingsheng He, Wenbin Fang, Qiong Luo, Naga K. Govindaraju, Tuyong Wang; from Hong Kong University of Science

and Technology; published in Proc. PACT 2008. It presents the design and implementation of MapReduce on graphics processors.

- "A Peer-to-Peer Framework for Supporting MapReduce Applications in Dynamic Cloud Environments" (http://www.springerlink.com/content/h17r882710314147/) — paper by Fabrizio Marozzo, Domenico Talia, Paolo Trunfio; from University of Calabria; published in Cloud Computing: Principles, Systems and Applications, N. Antonopoulos, L. Gillam (Editors), chapt. 7, pp. 113–125, Springer, 2010, ISBN 978-1-84996-240-7.
- "Map-Reduce-Merge: Simplified Relational Data Processing on Large Clusters" (http://portal.acm.org/citation.cfm?doid=1247480.1247602) — paper by Hung-Chih Yang, Ali Dasdan, Ruey-Lung Hsiao, and D. Stott Parker; from Yahoo and UCLA; published in Proc. of ACM SIGMOD, pp. 1029–1040, 2007. (This paper shows how to extend MapReduce for relational data processing.)
- FLuX: the Fault-tolerant (http://citeseer.ist.psu.edu/647742.html), Load Balancing (http://citeseer.ist.psu.edu/546646.html) eXchange operator from UC Berkeley provides an integration of partitioned parallelism with process pairs. This results in a more pipelined approach than Google's MapReduce with instantaneous failover, but with additional implementation cost.
- "A New Computation Model for Rack-Based Computing" (http://infolab.stanford.edu/~ullman/pub/mapred.pdf) — paper by Foto N. Afrati; Jeffrey D. Ullman; from Stanford University; Not published as of November 2009. This paper is an attempt to develop a general model in which one can compare algorithms for computing in an environment similar to what map-reduce expects.
- FPMR: MapReduce framework on FPGA (http://portal.acm.org/beta/citation.cfm?id=1723112.1723129) — paper by Yi Shan, Bo Wang, Jing Yan, Yu Wang, Ningyi Xu, Huazhong Yang (2010), in FPGA '10, Proceedings of the 18th annual ACM/SIGDA international symposium on Field programmable gate arrays.
- "Tiled-MapReduce: Optimizing Resource Usages of Data-parallel Applications on Multicore with Tiling" (http://ipads.se.sjtu.edu.cn/lib/exe/fetch.php?media=publications:ostrich-pact10.pdf) — paper by Rong Chen, Haibo Chen and Binyu Zang from Fudan University; published in Proc. PACT 2010. It presents the Tiled-MapReduce programming model which optimizes resource usages of MapReduce applications on multicore environment using tiling strategy.
- "Tiled MapReduce: Efficient and Flexible MapReduce Processing on Multicore with Tiling" (http://ipads.se.sjtu.edu.cn/lib/exe/fetch.php?media=publications:ostrich-taco13.pdf) — paper by Rong Chen, and Haibo Chen from Shanghai Jiao Tong University; published in ACM TACO, 10(1), 2013. It extends the earlier version of Ostrich to support several usage scenarios such as online and incremental computing on multicore machines.
- "Scheduling divisible MapReduce computations " (http://dx.doi.org/10.1016/j.jpdc.2010.12.004) — paper by Joanna Berlińska from Adam Mickiewicz University and Maciej Drozdowski from Poznan University of Technology; Journal of Parallel and Distributed Computing 71 (2011) 450-459, doi:10.1016/j.jpdc.2010.12.004 (https://dx.doi.org/10.1016%2Fj.jpdc.2010.12.004). It presents scheduling and performance model of MapReduce.
- "Nephele/PACTs: A Programming Model and Execution Framework for Web-Scale Analytical Processing" (http://stratosphere.eu/files/NephelePACTs_10.pdf) — paper by D. Battré, S. Ewen, F. Hueske, O. Kao, V. Markl, and D. Warneke from TU Berlin (http://www.tu-berlin.de/menue/home/parameter/en/) published in Proc. of ACM SoCC 2010. The paper introduces the PACT programming model, a generalization of MapReduce, developed in the Stratosphere (http://www.stratosphere.eu) research project.
- "MapReduce and PACT - Comparing Data Parallel Programming Models"

(http://stratosphere.eu/files/ComparingMapReduceAndPACTs_11.pdf)—paper by A. Alexandrov, S. Ewen, M. Heimel, F. Hueske, O. Kao, V. Markl, E. Nijkamp, and D. Warneke from TU Berlin (http://www.tu-berlin.de/menue/home/parameter/en/) published in Proc. of BTW 2011.

Books

- Jimmy Lin and Chris Dyer. "Data-Intensive Text Processing with MapReduce" (http://www.umiacs.umd.edu/~jimmylin/book.html) (manuscript)

Educational courses

- Cluster Computing and MapReduce (http://code.google.com/edu/submissions/mapreduce-minilecture/listing.html) course from Google Code University (http://code.google.com/edu/) contains video lectures and related course materials from a series of lectures that was taught to Google software engineering interns during the Summer of 2007.
- MapReduce in a Week (http://code.google.com/edu/submissions/mapreduce/listing.html) course from Google Code University (http://code.google.com/edu/) contains a comprehensive introduction to MapReduce including lectures, reading material, and programming assignments.
- MapReduce course (http://mr.iap.2008.googlepages.com/), taught by engineers of Google Boston, part of 2008 Independent Activities Period at MIT.

Bibliography

- MapReduce bibliography by A. Kamil, 2010 (http://www.columbia.edu/~ak2834/mapreduce.html)
